</table>
The Human Immunodeficiency Virus (HIV) is a virus that can be spread through sexual contact, needle-sharing, and from a woman to her child through pregnancy, birth, and breastfeeding. While HIV is not a curable infection, people living with HIV who are in medical care and are taking their medications can achieve an undetectable HIV viral load and have a normal life expectancy. If left untreated, HIV infection can lead to acquired immunodeficiency syndrome, or AIDS. Because the immune system is greatly weakened for people diagnosed with AIDS, those living with AIDS have an increased susceptibility to certain infections and cancers that can potentially result in death.

**FIGURE 1**

**Number of Newly Diagnosed Cases of HIV, Rhode Island, 2010-2019**

Over the last 10 years, there has been an overall reduction in the number of newly diagnosed cases of HIV in Rhode Island. There has been a slight increase from 2015 through 2019, however, the number of cases in 2018 and 2019 remained stable.

**HIV/AIDS Deaths**

Since 1983, a total of 1,854 deaths have occurred among Rhode Island residents diagnosed with HIV/AIDS. However, only 185 (9.9%) of those deaths occurred from 2014-2018, and deaths decreased annually in this five-year period. Between 2010 and 2017, the national age-adjusted rate of HIV-related deaths fell by nearly half. This reduction in deaths underscores the impact of improved treatment and access to care for people living with HIV (PLWH).
It is estimated that 2,674 Rhode Islanders were diagnosed and living with HIV through the end of 2018. It is also estimated that about 11% of individuals who are HIV-infected do not know their status, which suggests the numbers above are an underestimate of all Rhode Islanders living with HIV. Due to advances in HIV treatment, people who are HIV-positive are living longer lives and represent a growing segment of Rhode Island’s population. The numbers above also reflect the migration of people living with HIV who migrate into and out of the state.

Over the last 10 years, amongst those with a known mode of exposure, slightly more than half (54.6%) of newly diagnosed cases of HIV were among gay, bisexual, or other men who have sex with men (GBMSM). Meanwhile, the number of newly diagnosed cases of HIV among heterosexual males and females, as well as persons who inject drugs (PWID), has remained low. In 2019, there were almost 3 times as many cases of HIV among GBMSM when compared to females, male heterosexuals, and PWID, combined. Figure 3b provides a snapshot of the five-year period of 2015-2019.
From 2015 to 2019, the predominant (91%) mode of HIV exposure among newly diagnosed HIV cases was sexual contact, followed by MSM/IDU (6%) and IDU (3%). GBMSM represent the majority (72%) of individuals among those with sexual contact as a mode of exposure. There was no reported transmission of HIV from pregnant HIV+ women to their babies during this time.

**Intravenous Drug Use**

HIV infection associated with intravenous drug use (IDU) has decreased substantially in the last 20 years. In the last five years, just over 3% of newly-diagnosed cases were attributed strictly to IDU. A significant factor in the success of reducing IDU transmission is the ENCORE (Education, Needle Exchange, Counseling, Outreach and Referral) Program that has been operating in Rhode Island since 1995.

**Mother-to-child HIV Transmission**

A Rhode Island public health success has been the virtual elimination of HIV among babies born to mothers who are HIV positive. This success is due in large part to the routine HIV testing of pregnant women and anti-retroviral treatment therapy, when indicated as part of prenatal care. There have been zero reported cases of mother-to-child transmission in the last five years.

Source: Rhode Island Department of Health
From 2015-2019, about 21% of individuals newly diagnosed with HIV in Rhode Island also had a concurrent HIV stage 3 (AIDS) diagnosis. The average time from untreated HIV infection to development of stage 3 infection is eight years. During this time, undiagnosed HIV-positive individuals could have benefitted from treatment that would have benefited their health outcomes. Because many people with HIV do not have any symptoms, undiagnosed HIV-positive individuals may also unknowingly transmit HIV to others.

In the past five years, the rates of newly diagnosed HIV cases were highest among Rhode Islanders in their 20s, 30s, and 40s. Rates among individuals ages 20-29 and 30-39 have remained consistently high compared to other groups, although from 2018 to 2019 there was 50% increase in cases in those ages 30-39. This is a continuation of a gradual increase in cases in this age group over the last five years.
In 2016, Rhode Island signed on to the International Association of Providers of AIDS Care (IAPAC) Fast-Track Cities Initiative. This initiative is a global partnership with local municipalities, IAPAC, the Joint United Nations Programme on HIV/AIDS (UNAIDS), the United Nations Human Settlements Program (UN-Habitat), and the City of Paris. The goal of this initiative is to attain the UNAIDS 90-90-90 targets, which include: 90% of all people living with HIV in Rhode Island will know their HIV status, 90% of all people with diagnosed HIV infection will receive sustained antiretroviral therapy (ART), and 90% of all people receiving ART will achieve viral suppression.

The Rhode Island HIV Care Continuum is a visual representation of the care status of individuals diagnosed with HIV that reside in Rhode Island. Engagement in care is used as a proxy measure for receiving sustained ART. As the Care Continuum below indicates, Rhode Island has made progress on its 90-90-90 goals: 89% of Rhode Islanders who are HIV positive know their status, 74% of Rhode Islanders living with HIV are engaged in care, and 69% of Rhode Islanders living with HIV have achieved viral suppression.

When considering only those who have been diagnosed with HIV, 83% are engaged in care and 77% are virally suppressed.

Nationally, from 2010 to 2018, the number of Americans who knew their HIV status increased from 82% to an all-time high of 86%, and the number of people with diagnosed HIV who had a suppressed viral load increased from 46% to nearly 65%. Rhode Island is currently surpassing these national averages as a result of a multifaceted approach to re-engagement and retention in care for people living with HIV (PLWH).

To help track Rhode Island’s efforts and ensure accountability and transparency, RIDOH provides quarterly updates on 90-90-90 progress online at www.health.ri.gov/909090.

**FIGURE 6**

**Rhode Island HIV Care Continuum, 2019**

* Prevalence estimates derived by using HIV surveillance and CD4 data for persons aged ≥13 years at diagnosis. Estimates rounded to the nearest 100 for estimates of >1,000 to reflect model uncertainty. Reflects estimated number of people living with HIV, both diagnosed and undiagnosed, at the end of 2019.

1 The number of people diagnosed with HIV (“know their status”) reflects persons diagnosed through 2018 and alive through the end of 2019 with most recent residence in Rhode Island.

2 Receipt of care any care is defined as at least one care visit during the calendar year (2019).

3 A viral load (VL) test result of < 200 copies per milliliter (c/ml) of blood represents HIV viral suppression. VL test results are from the most recent test during the specified year (2019).
Syphilis is an infection caused by bacteria that is spread through sexual contact. While syphilis is a treatable disease, people can become re-infected if their partners are not treated. Untreated syphilis can lead to serious long-term health outcomes, including cardiac and neurological problems. Untreated syphilis in pregnant women can lead to stillbirths and infant deaths. Untreated babies may become developmentally delayed, experience seizures, and die. Once diagnosed, syphilis is curable with antibiotics.

**FIGURE 7**

*Number of Infectious Syphilis Cases, Rhode Island, 2010-2019*

Infectious syphilis is defined as infection within the past year (primary, secondary, or early latent stages) when people are most likely to transmit the infection to others. From 2010-2019, there was a 244% increase in infectious syphilis cases, from 61 cases in 2010 to 210 cases in 2019.

Source: Rhode Island Department of Health
From 2015-2019, people in their 20s and 30s had the highest infectious syphilis rates in Rhode Island. No babies were born with congenital syphilis in the last five years.
Gonorrhea is an infection caused by bacteria that is spread through sexual contact. While gonorrhea is treatable, there are increasing public health concerns about strains of gonorrhea in the United States that are resistant to standard medications. If left untreated, gonorrhea can have reproductive health consequences for women. Pregnant women can transmit gonorrhea to their newborn babies, resulting in health problems for the child.

FIGURE 10
Number of Gonorrhea Cases, Rhode Island, 2010-2019

Since 2010, rates of gonorrhea have increased by 421% in Rhode Island. This increase may be partially attributed to increases in extragenital testing (i.e., testing of the throat and rectum) for gonorrhea by Rhode Island providers in recent years.

Source: Rhode Island Department of Health
In the last 10 years, more gonorrhea cases have been observed in males than in females. This is likely attributable to the severity of symptoms among males and an increase in gonorrhea in the GBMSM population.

From 2010-2019, case rates for gonorrhea were consistently highest among people in their 20s, followed by people in their 30s.
05 | CHLAMYDIA

Chlamydia is an infection caused by bacteria that is spread through sexual contact. While chlamydia is treatable, people can get re-infected if their partners are not treated. Untreated chlamydia can lead to serious health problems, especially among young women, including pelvic inflammatory disease, ectopic pregnancy, and infertility.

FIGURE 13
Number of Chlamydia Cases, Rhode Island, 2010-2019

In the last 10 years, the number of chlamydia cases has increased by 64% from 3,480 cases in 2010 to 5,717 cases in 2019.

Source: Rhode Island Department of Health
Most chlamydia cases in the last 10 years have been diagnosed in females. In 2019, nearly twice as many cases were diagnosed in females than in males. This difference is likely due to more frequent health care access/screening among women and the lack of symptoms among men.

From 2015-2019, the highest rates of chlamydia were in people in their 20s, followed by people age 19 or younger, followed by people in their 30s. Rates in people in their 20s have increased over the last five years.
VIRAL HEPATITIS

Hepatitis refers to inflammation of the liver. When the liver is inflamed or damaged, its function can be affected. Hepatitis can be caused by heavy alcohol use, toxins, some medications, and certain medical conditions. However, hepatitis is also caused by several viruses. The most common types of viral hepatitis in the United States are hepatitis A, hepatitis B, and hepatitis C. Importantly, Hepatitis C Virus (HCV) is the most common blood-borne infection in the United States. It is estimated that 3.2 million Americans are chronically infected.² Chronic HCV infection increases the risk for hepatic fibrosis, cirrhosis, and hepatocellular carcinoma and is the most common reason for needing a liver transplant.

An estimated 16,603 to 22,660 people in Rhode Island (approximately 2% of Rhode Islanders) have been infected with HCV.³ Roughly 20% of those infected with HCV will clear their infection without any treatment. The remaining 80% are at risk of developing chronic disease. In the United States, the highest risk group for HCV infection is people who inject drugs, followed by individuals born between 1945 and 1965 (also known as baby boomers).

Figure 16 shows hospitalizations with any discharge diagnosis of HBV, HCV, or HIV. Discharge diagnosis of HCV remained consistently higher than HIV and HBV hospitalizations during the past decade.

FIGURE 16
Number of Inpatient Hospitalizations with Any Discharge Diagnosis of HBV, HCV, or HIV, Rhode Island, 2010-2019

Source: Rhode Island Department of Health
In Rhode Island, like national trends, the annual number of deaths attributed to HCV in recent years surpassed the number of deaths attributed to HIV and 59 other nationally notifiable infectious diseases, combined.⁴

Over the past few years, there have been advances in treatment options and improvements in healthcare access for people living with HCV infection. An increase in the availability of direct-acting antiviral (DAA) medication, which are more effective, safer, and better tolerated than previous HCV therapies, will improve cure rates for people living with HCV and reduce the morbidity and mortality associated with HCV.
Tuberculosis (TB) is a disease caused by a bacterium called Mycobacterium tuberculosis. TB can be spread from one person to another through the air. When someone with active TB disease in the lungs or throat coughs, sings, or even speaks, TB bacteria can be released into the air and can stay in the air for hours.

Active TB can be within the lungs (pulmonary) or outside the lungs (extrapulmonary). Common symptoms of active TB disease include fever, cough, and weight loss. Diagnosis may involve chest imaging and sputum and/or tissue collection for smear, nucleic acid amplification (NAAT), and/or culture testing. Drug susceptibility testing is often performed to determine the best course of treatment.

Latent TB infection (LTBI) is the presence of M. tuberculosis in the body without signs or symptoms, radiographic, or bacteriologic evidence of TB disease. While not everyone with LTBI will develop active TB disease, about 5-10% of infected people will develop TB disease if not treated. HIV infection, injection drug use, low body weight, and other medical conditions are risk factors associated with progression from LTBI to TB disease.

Over the last 10 years, the number of reported cases of active tuberculosis has remained relatively low, ranging from 12 to 30 cases. Over the last five years, the rate of active TB in Rhode Island has remained under 3 cases per 100,000 population.
Demographic Characteristics of Active Tuberculosis Cases (n=14), 2019

**SEX**
- **57%** Female
- **43%** Male

**AGE**
- 0-25 YEARS: 0 (0%)
- 25-44 YEARS: 6 (43%)
- 45-64 YEARS: 4 (28.5%)
- 65+ YEARS: 4 (28.5%)

Country of Birth
- United States: 7.1%
- Central America and Caribbean: 21.4%
- Asia: 50.0%
- Africa: 21.4%
- Europe: 0.0%

**CLINICAL CHARACTERISTICS - 2019**
- **85.7%** Proportion of TB cases with pulmonary disease
- **57.1%** Proportion of TB cases with a positive culture
- **42.8%** Proportion of TB cases with a positive sputum smear

**Tuberculosis Drug Resistance**

TB resistance occurs when people are infected with a drug resistant strain, receive suboptimal TB medication regimens, or receive incomplete treatment. Multi-drug resistant TB (MDR-TB) and extensively-drug resistant TB (XDR-TB) are rare and more severe kinds of TB that are also resistant to first and second-line medications, such as fluoroquinolones. It is important to diagnose and treat MDR-TB appropriately to prevent further transmission of drug-resistant disease. In 2019, 57% of cases were confirmed by culture; of them, 0% were resistant to only one drug and 25% were multi-drug resistant.

---

**RIDOH TB Directly Observed Therapy Program**

RIDOH has two over-arching priorities to prevent TB transmission in Rhode Island.

1. Treat all active cases to ensure all patients are cured and prevent transmission to others.

2. Assure adherence to therapy, which can take up to 9 months or longer, to prevent the development of antibiotic-resistant strains of TB.

To achieve these goals and assure that patients are adherent to their medications, RIDOH operates a universal directly-observed-therapy (DOT) program for all people diagnosed with active TB disease in Rhode Island. This program includes regular visits to patients’ homes (or internet-based video submissions) to ensure ingestion of TB medication. These visits continue for the entire duration of patients’ care, which can last up to nine months. Over the last 10 years, the DOT program has had an average medication administration success rate of 98%.
Latent TB Infection (LTBI)

In Rhode Island it is estimated that about 15,000-20,000 individuals are living with latent TB infection (LTBI). It is important to identify LTBI cases and promote initiation and completion of treatment to reduce the number of individuals who have LTBI that subsequently become active TB cases. LTBI has been reportable in Rhode Island since 2010.
According to the CDC, acknowledging the inequities in STD and HIV rates by race and ethnicity is one of the first steps in addressing these disparities. The factors contributing to these health inequities are complex and can include poverty, income inequality, access to healthcare, and stigma/discrimination. Another contributing factor is that in communities where STD prevalence is higher, individuals face a greater chance of encountering an infected partner than those in lower-prevalence settings.

**FIGURE 21**
Rates of Newly Diagnosed Cases of HIV, by Racial and Ethnic Group, Rhode Island, 2015-2019

While HIV diagnoses have decreased overall in the last 10 years, disparities in HIV rates among racial and ethnic groups in Rhode Island persist. When compared to whites, in 2019 the rates of HIV were over six times higher among Blacks/African Americans, and over twice as high among Hispanics/Latinos.
Infectious syphilis diagnoses have increased in the last 10 years and disparities in syphilis rates among racial and ethnic groups in Rhode Island have expanded. When compared to whites, in 2019 the rates of infectious syphilis were nearly three times higher among both Blacks/African Americans and Hispanic/Latinos.

Gonorrhea diagnoses have increased in the last 10 years and disproportionately affect the Black/African American population. In 2019, gonorrhea rates were about seven times higher among Blacks/African Americans as compared to whites, and about twice as high as among Hispanics/Latinos.
Chlamydia diagnoses have steadily increased in the last 10 years and disproportionately affect the Black/African American population. In 2019, chlamydia rates were nearly seven times higher among Blacks/African Americans as compared to whites.

Source: Rhode Island Department of Health
In addition to the biological factors that place females at a higher risk of STDs, females may be less likely to negotiate safer sexual practices, such as condom use, than males. These social factors can significantly affect a female’s sexual and reproductive health and subsequently, the health of her newborn baby.

**FIGURE 25**

Rates of Chlamydia in Females, by Age, Rhode Island, 2015-2019

![Graph showing chlamydia rates by age and year.](image)

Source: Rhode Island Department of Health

Over the past five years, rates of chlamydia in females have remained highest in the 20-29 age group, followed by the 19 and younger age group. In 2019, the rate of chlamydia among females in their 20s was nearly three times higher compared to any other age group.
Through the Healthcare Effectiveness and Data Information Set (HEDIS), insurance claim data are used to calculate annual estimates of the percentage of sexually active females, age 16-24, who are screened for chlamydia. Commercial Health Plans include data from Blue Cross Blue Shield of Rhode Island, United Health Care, and Neighborhood Health Plan; Medicaid plans include data from Tufts Health, Neighborhood Health Plan, and United Health Care. In 2019 in Rhode Island, 67% of women enrolled in Medicaid and 66% of women enrolled in commercial health plans were screened for chlamydia. These figures are well above the national averages. Nationally, in 2018, 54% of women enrolled in Medicaid and 44% enrolled in commercial health plans were screened for chlamydia (National Committee for Quality Assurance).

**FIGURE 26**
Screening for Chlamydia in Females Age 16-24, by Insurance Plan, Rhode Island, 2015-2019

Source: Rhode Island Department of Health

HIV Risk Factors and Females

Characteristics of the 74 females that were newly diagnosed with HIV in Rhode Island from 2015 to 2019 include:

- Born outside of the United States: 66%
- Sex with someone known to be HIV positive: 22%
- Exchanged sex for money, drugs, goods, or services in their life: 6%
- Sex while high or intoxicated: 15%
- Forced to have sex involuntarily in their life: 14%
- Injected non-prescription drugs in their life: 10%
- History of incarceration: 11%
Legislation permitting Expedited Partner Therapy (EPT) was passed in Rhode Island in 2006. This legislation allows physicians to prescribe prescription drugs for a patient's sexual partners without evaluating or testing their patients' partners. The CDC recommends EPT as a useful option to facilitate partner management particularly for treatment of male partners of women with chlamydial infection. The percentage of chlamydia patients offered EPT declined from 34% to 28% between 2017 and 2019. The percentage of those who accepted EPT among those offered was similar to the previous two years.

Source: Rhode Island Department of Health
Offer and acceptance of EPT based on provider report on the RIDOH STD Case Report Form
The relatively high incidence of STD infection among GBMSM may be related to multiple factors, including individual behaviors and sexual network characteristics. The number of lifetime or recent sex partners, rate of partner exchange, and frequency of condomless sex each influence an individual’s probability of exposure to STDs. However, GBMSM network characteristics such as high prevalence of STDs, interconnectedness and concurrency of sex partners, and possibly limited access to health care, also affect the risk of acquiring an STD. Furthermore, experiences of stigma — verbal harassment, discrimination, or physical assault based on attraction to men — are associated with increased sexual risk behavior among GBMSM.

**FIGURE 28**
Rates of Newly Diagnosed Cases of HIV in Males, by Mode of Sexual Exposure, Rhode Island, 2015-2019

In the last five years, the rates of newly diagnosed cases of HIV among GBMSM have been substantially higher than heterosexual men.
From 2015-2019, there has been an increase in the number of newly diagnosed cases of HIV in GBMSM in their 20s and 30s. Like other areas in the United States, young gay and bisexual Black/African American and Hispanic/Latino men in Rhode Island have been increasingly affected by HIV.

Gonorrhea and the GBMSM Population

Information collected through interviews with men in Rhode Island diagnosed with gonorrhea indicates that approximately 54% of the males identified as GBMSM in 2019, compared to 35% in 2014. Some of the increase may be due to an increase in extragenital testing in GBMSM, which is detecting more gonorrhea cases that would have been missed in previous years.
Infectious syphilis was diagnosed in the GBMSM population at a rate nearly 150 times higher than in the heterosexual male population in 2019. Over the last five years this trend has been observed consistently.

A substantial percentage of GBMSM diagnosed with infectious syphilis in recent years are also living with HIV. Of the 139 GBMSM who had infectious syphilis in 2019, 50 individuals were HIV-positive. HIV-positive men who are co-infected with infectious syphilis are more likely to spread HIV to their sexual partners than HIV-positive men who do not have infectious syphilis.
According to the CDC, prevalence estimates suggest that young people (ages 15–24) account for half of all newly diagnosed STDs and that 25% of sexually active adolescent females have acquired an STD. Compared with older adults, sexually active young people are at higher risk of acquiring STDs due to a combination of behavioral, biological, and cultural reasons. The higher prevalence of STDs among adolescents also may reflect multiple barriers to accessing quality STD prevention services, including inability to pay, lack of transportation, discomfort with facilities and services designed for adults, and concerns about confidentiality.

Between 2015-2019, among young adults, there were three female cases and 48 male cases. Among the 48 young adult male cases, 96% were GBMSM (N=46).

Overall, males outnumbered females in the number of newly diagnosed cases of HIV among young adults (18-24) in Rhode Island by a ratio of 16:1.

The incidence of both chlamydia and gonorrhea among people ages 15-24 far exceeded the state rate for the last five years.
Youth Risk Behavior Survey

The Youth Risk Behavior Survey (YRBS) is an anonymous and voluntary, self-administered survey conducted every two years among random samples of high school students in Rhode Island. Its purpose is to monitor risk behaviors related to the major causes of mortality, disease, injury, and social problems among youth in the United States.

In 2019, Rhode Island high school students reported more sexual risk-taking behavior than high school students nationally based on three questions included on the survey. In previous years, Rhode Island students have reported less risk-taking behaviors than high school students nationally. The 2019 United States data was reported as part of the YRBS that is administered through the CDC.

Source: CDC Youth Risk Behavior Survey, Rhode Island, 2019

The Rhode Island high school students participating in the 2019 YRBS self-identified as follows:
- heterosexual (84%)
- gay or lesbian (3%)
- bisexual (9%)
- not sure (5%)
Rhode Island Department of Health began distributing human papilloma virus (HPV) vaccine for girls in 2006 and for boys in 2010. In 2019, Rhode Island had a high coverage rate for at least one dose of HPV vaccine for both boys (90.5%) and girls (93.4%) ages 13-17. HPV is transmitted through contact with infected skin, usually through sexual contact. HPV vaccine protects individuals from HPV infection, which can cause warts in the genital area and/or lead to abnormal cells on the cervix, vulva, anus, penis, mouth, and throat, sometimes leading to cancer. The vaccine is most effective when given before young people engage in sexual activity.

Source: Rhode Island Department of Health
There are many behavioral risk factors that place a sexually active individual at risk for acquiring an STD. These behavioral factors include, but are not limited to: gender of partners, condom use, number of sexual partners, alcohol/substance abuse (in combination with sex), and type of sexual practices (oral, vaginal, anal). Trends in HIV and STD rates are often associated with changes in these behavioral risk factors. Insights into these behaviors can be obtained through findings from the Rhode Island Behavioral Risk Factor Surveillance System (BRFSS) conducted by RIDOH in collaboration with the CDC. Below are highlights from the most recent survey administered in 2019.

**FIGURE 38**

Breakdown of Sexual Orientation, Rhode Island, 2019

**Sexual Activity of Adults (18-64) in the Past Year, Rhode Island, 2019**

Out of 100 Rhode Islanders in the past 12 months:

- **10** people had two or more sexual partners
- **70** people had one sexual partner
- **20** people had no sex partners
Characteristics of Adults (18-64) with Multiple Sex Partners, Rhode Island, 2019

- **56%** used a condom at last sexual intercourse
- **58%** received an STD test within the past 12 months*
- **63%** have ever received an HIV test

*This question reads “Have you been tested for a Sexually Transmitted Disease or venereal disease in the past 12 months?”

GEOGRAPHIC DISTRIBUTION OF HIV/STDs IN RHODE ISLAND

While cases of HIV and STDs have been reported in every city and town in Rhode Island, higher case counts, and concentrations of HIV/STDs are generally found in more urban settings. Below is a ranking of the Rhode Island municipalities that have the highest number of cases of HIV and STDs.

For more information on the distribution of HIV and STDs in Rhode Island or for additional municipality information, please refer to Appendix 1: Geographic Burden of HIV and STDs in Rhode Island or contact the Center for HIV, Hepatitis, STD, and TB Epidemiology at 401-222-2577.
Behavioral Risk Factor Surveillance System (BRFSS): The BRFSS is a survey of non-institutionalized adults (age 18 years or older) and is administered by telephone to a random-digit-dialed sample of cell phones and landlines. Data from the sample are weighted to obtain state population-level estimates.

Gay, Bisexual, and Other Men Who Have Sex with Men (GBMSM): For the purposes of this report, GBMSM includes all men who have sex with men. This classification indicates a sexual behavior that is a risk factor for transmitting HIV and other STDs and not how individuals self-identify in terms of their sexuality.

Extragenital testing: Traditional methods of testing for gonorrhea and chlamydia include urine-based, cervical, or vaginal tests. STDs can infect various parts of the body and traditional tests cannot always identify infections in other areas of the body. Depending on sexual behavior, individuals may be infected in the throat or rectum. Swab-based tests of the throat and rectum can identify gonorrhea and chlamydia infections of those sites and allow for proper treatment.

Expedited Partner Therapy (EPT): For some chlamydia cases, a doctor may prescribe EPT for the patient’s sexual partner(s) when it is unlikely the partner will be tested and treated. The CDC recommends EPT as a useful option to facilitate partner management, particularly for treatment of male partners of women with chlamydial infection.

Healthcare Effectiveness and Data Information Set (HEDIS): HEDIS is a dataset managed by the National Committee for Quality Assurance that is used by healthcare plans to monitor performance for certain aspects of healthcare. For STDs, this includes insurance claim data that is used to calculate yearly estimates for the percentage of sexually active females, age 16-24, that are screened for chlamydia. Medicare data from UnitedHealthcare and Neighborhood Health Plan of Rhode Island are used to calculate chlamydia screening estimates for Rhode Island. Commercial health plan data is obtained from Blue Cross & Blue Shield of Rhode Island and UnitedHealthcare. These four plans account for most health insurance providers in Rhode Island.

HIV/AIDS and STD surveillance data: All HIV/AIDS and STD data are collected from case and laboratory reports received from healthcare providers, laboratories, and other entities in accordance with the Rhode Island Rules and Regulations Pertaining to Reporting of Infectious, Environmental and Occupational Diseases [R23-10-DIS].

HIV/AIDS Exposure Categories: For each new case of HIV, risk is ascertained by medical providers and RIDOH Partner Services staff. “High Risk Heterosexual” exposure for males refers to a male whose primary risk is that he has had sex with a female who is known to have HIV or engage in intravenous drug use. “High Risk Heterosexual” exposure for females refers to a female whose primary risk is that she has had sex with a male who is known to have HIV or engage in intravenous drug use. “Presumed Heterosexual” refers to a female whose only known risk is sex with a male with unknown HIV status. When a male’s only identified risk is sex with a female whose HIV status is not known, this is considered “No Reported Risk”. When risk/exposure data is presented, cases with “Unknown” risk are not shown – these include cases of “No Reported Risk” and “No Identified Risk” (cases who report not having engaged in any behaviors where transmission is possible, such as sexual activity, intravenous drug use, or blood transfusions).

Infectious syphilis: Includes primary, secondary, and early latent stages.

Population-based rate calculations: Rates are expressed as cases per 100,000 population. All rates for 2013-2017 are based on the 2017 US Census, except rates by municipality which are based on the 2016 American Communities Survey.

Race/ethnicity: Surveillance data is routinely collected and analyzed for all racial and ethnic groups, including American Indian/Alaskan Native, Asian, Black/African American, Hispanic or Latino, Native Hawaiian/Pacific Islander, and White. Individuals may be categorized as multi-race or other racial categories. The following conventions were used when reporting racial and ethnic data in this report:

1. Individuals classified as Hispanic or Latino represent individuals who may have also identified as another racial group.
2. Individuals classified as White or Black/African American represent only those individuals who also identified as non-Hispanic.
3. Omission of certain racial/ethnic groups (American Indian/Alaskan Native, Asian, and Native Hawaiian/ Pacific Islander) from this report has been done to protect the privacy and confidentiality of those populations that have small case counts and population sizes. Please contact RIDOH’s Center for HIV, Hepatitis, STD, and TB Epidemiology for more information on these populations.

Youth Risk Behavior Survey (YRBS): A national, school-based survey funded by the CDC and conducted by state, territorial, and local education and health agencies and tribal governments.
DATA LIMITATIONS

BRFSS: The BRFSS relies on information reported directly by the respondent, which may have a potential for bias.

Population estimates for GBMSM: No standard estimate exists for the number of GBMSM that live in the United States or in an individual state. Research by Spencer Lieb et al and results from the BRFSS were used to estimate that 5% of the adult male population in Rhode Island identifies as gay or bisexual. Rates of disease for the GBMSM population were calculated using this estimate and data from the US Census.

Deaths attributed to HIV, HBV, and HCV: Vital status for cases of HIV is obtained by matching information from RIDOH’s Center for Vital Records, the National Death Index, and the Social Security Death Master File. Matching against national datasets is subject to availability and typically occurs one year after traditional case surveillance data are available. Thus, the most current complete death data available for this report is from 2018. HBV- and HCV-associated deaths in Rhode Island may include non-Rhode Island residents.

HIV/AIDS prevalence: Prevalence estimates are generated using the CDC’s CD4 Depletion Model, which is subject to various assumptions about data completeness and accuracy. Estimates are calculated using CDC-supplied SAS code and are based on data supplied to CDC by Rhode Island. Rhode Island’s data are based on multiple data sources. Vital status data received by RIDOH, the National Death Index, and Social Security Death Master File are used to identify individuals who are deceased, although these sources are subject to lag. Routine interstate review for duplicates is carried out semi-annually to identify cases who may have been reported in more than one jurisdiction and to ensure individuals are only counted once in the national dataset. Through a combination of duplicate review, ad-hoc record searches, and laboratory results, address information is updated on cases to better reflect current residence information, accounting for interstate and intrastate migration. In 2014, accounting for interstate migration was improved and the prevalence estimates from 2014 on have been updated with the new methodology.

Newly diagnosed cases of HIV versus incident cases of HIV: The data presented in this surveillance report represents newly diagnosed cases of HIV and not trends for new infection of HIV. Rhode Island, like all states and US territories, collects and reports data on persons diagnosed with HIV infection. However, because HIV diagnosis can occur at any point after infection, these estimates may not reflect all recent infections. Prevalence estimates are calculated using CDC-provided SAS code to provide estimates that include both those diagnosed as well as undiagnosed with HIV to understand the entire burden of HIV on the state.
